

ConTEXt

title : ConTEXt User Module
subtitle : Framework for Letters
author : Wolfgang Schuster
date : May 28, 2008

Constants and Variables

```

1 \writestatus{loading}{Context User Module / Framework for Letters}
2 \unprotect

I use a few extra constants and variables in my module.

3 \startconstants      all
4
5   graphic: graphic
6   head: head
7   foot: foot
8   backaddress: backaddress
9   topmark: topmark
10  botmark: botmark
11  cutmark: cutmark
12  endmark: endmark
13  usermark: usermark
14  foldmark: foldmark
15  extension: extension
16  interface: interface
17  backgroundimage: backgroundimage
18  whitespace: whitespace
19  optimize: optimize
20 \stopconstants

21 \startvariables      all
22
23  letter: letter
24  secondpage: secondpage
25  backaddress: backaddress
26  foot: foot
27  topmark: topmark
28  botmark: botmark
29  cutmark: cutmark
30  endmark: endmark
31  reference: reference
32  location: location
33  option: option
34  address: address
35  foldmark: foldmark
36  usermark: usermark
37  opening: opening
38  closing: closing
39  layer: layer
40  letternext: letternext
41  lettermain: lettermain
42  special: special
43  notation: notation
44  inside: inside
45 \stopvariables

```

Before we start the real module let us introduce two namespaces for the style and content setup commands.

```
7 \def\????ld{@@@@ld} % LetterData
\def\????ls{@@@@ls} % LetterStyle
\def\????lv{@@@@lv} % LetterValue

8 \startmodule[letter]

9 \setupmodule
  [\c!style=,           % default letter style
   \c!extension=,        % default letter extension
   \c!interface=default] % default letter interface
```

Setup commands

\setuplett... The layout for the first page could be set with the `firstpage` key and the layout for the second and all following pages with the `secondpage` key. You could use any key and value from \setuplayout to set your own letter layout.

```
\setupletterstyle [...,1...] [...,2...]
1   firstpage  secondpage
2   inherits from \setuplayout
```

The header and footer texts for the letter is set with the `header` and `footer` keys, the text itself I written as argument as one of the three keys. The command itself has no option to use different texts for odd and even pages (if you really want this in a letter) but you could solve this with the macro \doifoddpageelse, I will give you a short example below.

```
\setupletterstyle [...,1...] [...,2...]
1   header  footer
2   lefttext    = TEXT
     middletext = TEXT
     righttext   = TEXT
```

This setups could produce somtimes a unwanted result is you use a doublesided layout, because the values for `lefttext` and `righttext` change on odd and even pages their position, e.g. `righttext` will always go to the outer margin and `lefttext` to the inner margin. Let's you want the pagenumber always on the right side you could use the following code, you could adapt it to your own needs without problems.

```
\setupletterstyle
[header]
[lefttext=\doifoddpageelse\donothing\pagetext,
 righttext=\doifoddpageelse\pagetext\donothing]

Interface, Style and Extension files

\useletter..
\useletter..
\useletter..

This module provides different types of files beside the main module.
Two of them could be used by the user while the third is only used in this file but you're free to use but you should really now what you do.

Each of the files has it's own file extension, you have to use if you want to create such a file, this has the advantage to use the same name for a collection of macros.

```
26 \def\letter!suffix!style    {nls}
     \def\letter!suffix!extension{nle}
     \def\letter!suffix!interface{nli}
```

Let us begin now to talk about the different types of files.

letter interface

The letter interface provides the connection between the user and the inner macros, it is possible to write a letter without a interface but you will loose many of the nice features. The features itself are defined within the interface and try to help the user to write a letter in a simpler than the raw interface.

I want to show you the difference between the default interface and the raw backend with a simple example, just a opening, the content and a closing text.

The example with the default interface looks like:

```
\startletter
  [opening=Hello User,
   closing=Good luck with your own interface]
I will show you how you could write a letter with my letter module
and the difference between the default and the raw interface. The raw
interface is should be only used by a high level interface and not the
user but you're free to do it.
\stopletter
```

The same example with the raw interface looks like:

```
\startsetups[letter:opening]
Hello User
\stopsetups

\startsetups[letter:content]
I will show you how you could write a letter with my letter module
and the difference between the default and the raw interface. The raw
interface is should be only used by a high level interface and not the
user but you're free to do it.
\stopsetups

\startsetups[letter:closing]
Good luck with your own interface
\stopsetups
```

The interface itself is loaded with the `\useletterinterface` command but you could also use the optional argument for `\usemodule` to load it. The first is only used in this file but it makes sense to use it also in a wrapper file for your own interface.

```

\useletterinterface [...,*,...]

*   IDENTIFIER

27 \def\useletterinterface
    {\dosingleargument\douseletterinterface}

28 \def\douseletterinterface[#1]%
    {\def\dodouseletterinterface##1%
     {\readfile{##1.\letter!suffix!interface}\donothing\donothing}%
      \processcommalist[#1]\dodouseletterinterface}

```

letter extension

The second filetype this module supports are letterextensions, you could use it to save macros and other values you want to use in many without the need to put it always in the real letter.

A few reasons for a letterextension file are:

- The letter head from your company,
- your own macro for the reference line,
- labels you need in different files (see `label.nle`),
- ...

The syntax to load a letterextension file is the same as for a interface and you could also argument for `\usemodule`.

```

\useletterextension [...,*,...]

*   IDENTIFIER

29 \def\useletterextension
    {\dosingleargument\douseletterextension}

30 \def\douseletterextension[#1]%
    {\def\dodouseletterextension##1%
     {\readfile{##1.\letter!suffix!extension}\donothing\donothing}%
      \processcommalist[#1]\dodouseletterextension}

```

letter styles

After I mentioned above how to load a interface and extension I will now come to the most important extension for the module.

Letter styles are used to change the layout of the letter, set the values for layers and enable and disable common options. Although it is possible to do all these things in the letter itself it is better to save often used settings in a extra file you could load on demand and share between your letters.

You could load a style file in the same way as the other to files, the first is `\useletterstyle` and the second the optional argument for `\usemodule`.

```

\useletterstyle [...,*,...]

*   IDENTIFIER

31 \def\useletterstyle
    {\dosingleargument\douseletterstyle}

32 \def\douseletterstyle[#1]%
    {\def\dodouseletterstyle##1%
     {\readfile{##1.\letter!suffix!style}\donothing\donothing}%
      \processcommalist[#1]\dodouseletterstyle}

\lettersty.. \lettervalue The two commands \letterstylevalue and \lettervalue could be used to access the values for the keys used in the letterstyle settings and the letter values for information.

The rest of module contains only internal macros and other settings, you don't need them as a normal user but you look at the default.
